

Frontend Take Home Challenge

Description - Review Page

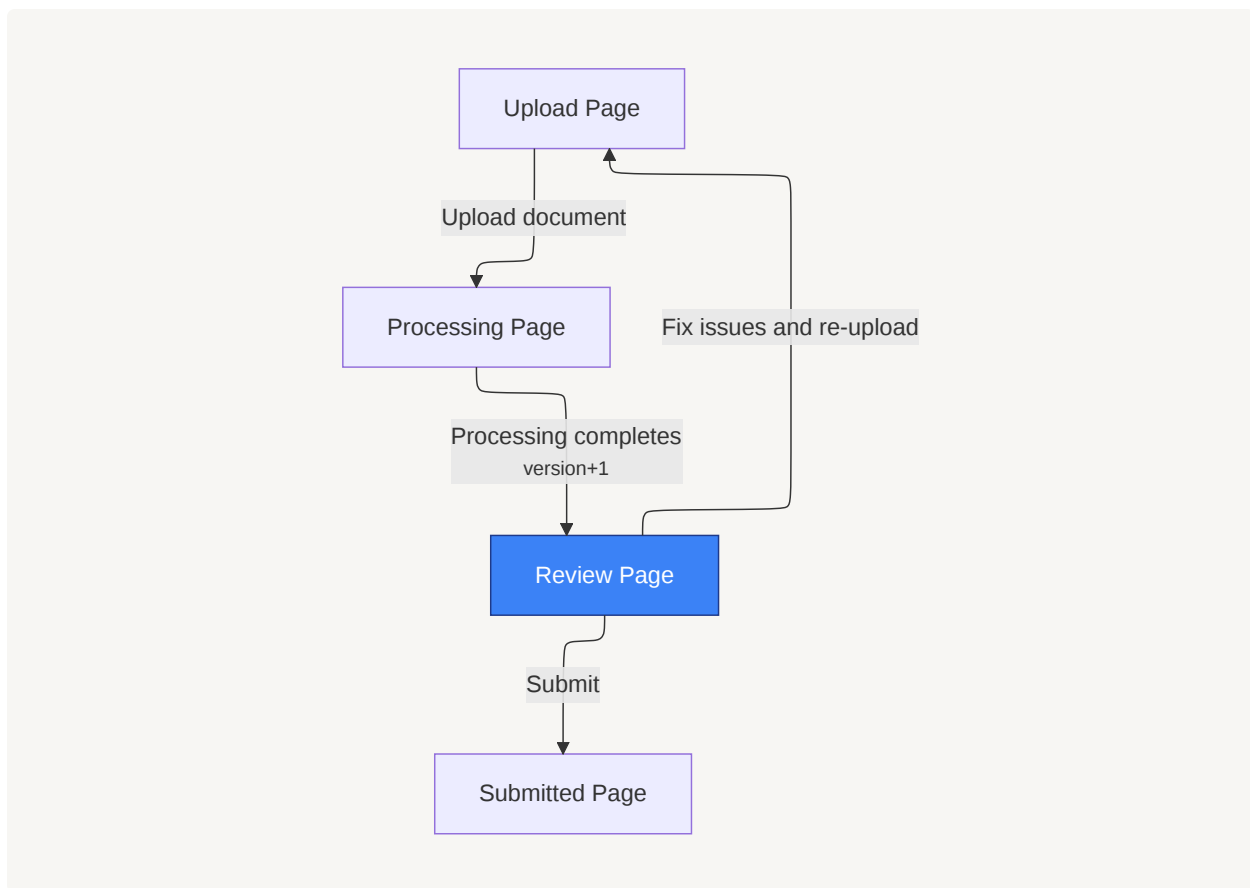

This is a take-home challenge for a Front-end Developer role at HomeVision. You'll build a page for a new product and decide how users interact with it.

We prefer React with TypeScript using frameworks like Vite or Next.js, but you're free to choose any UI component library.

Context

We're building a UI for our new Document Review product. You are an engineer on our team assigned to build the **Review Page**. Your teammates are working on the backend and the other pages.

Users upload documents that were created using an external application (for example, a PDF file). Our backend uses AI to process each document and identify issues that must be resolved before submission, such as fields that are missing data. Once all issues are addressed, the document can be submitted.

After a document is uploaded and processed, the user lands on the Review Page. This page shows all issues found during processing. The user must review and resolve all issues before submitting the review.

If the document has issues that must be resolved, users will return to their system, generate a new document, and upload the new version in our app. The backend will then process it again to create a new review.

This new review increments the version by 1 and includes only the latest uploaded document. The backend stores all versions of all documents, but for simplicity, it only returns the relevant data for the current version.

All issues are classified into three types: **critical**, **major**, and **minor**. Critical and major issues must be resolved before submitting. That means users need to fix those issues in their system and upload a new file. Minor issues can be ignored, so if a review has only minor issues, it can be submitted.

Once all issues are critical and major issues have been resolved, the review can be submitted.

Ticket - Review Page

Create the Review page so users can see the issues encountered with the document, understand what needs to be fixed, and submit the review once the review process is complete. Since the submit endpoint is not ready yet, we can skip the backend API call.

API

In this scenario, the API is not ready yet, but you can mock the endpoint response using the example below.

```
review_mock.json
```

Response fields

- **name:** the name of the file.
- **uploaded_at:** the date-time of the latest version upload
- **status:** the review status, options are `created`, `processing`, `on_review`, `submitted`.
- **version:** increments each time a new document version is uploaded.
- **user:** the user assigned to this document. For this MVP it's just the user that uploaded the document.
- **issues:** a list of problems the backend identified in the current document, along with the page where each issue appears.
- **document:** the URL to the PDF, plus a list of pages with each page number and its stored size.

Example Document

This is an example of what users upload. The documents format and length may vary depending on each case.

If you look at the `json mock`, you'll notice that the backend returns the URL for this file. You can replace that example URL with the path to the local file.

example_document.pdf

Acceptance Criteria

- Users should be able to see the document and search for text across the entire PDF using `CMD+F` / `Ctrl+F`.
- Users cannot submit the review until all **critical** and **major** issues are resolved. Minor issues may be ignored.
- The page should clearly communicate what's blocking submission.

Notes

- The design is up to you.

Project Requirements

- Design and implement a front-end App to display the Review Page.
- Use React and TypeScript if possible.

Bonus Points

- Tell us about your development approach and what aspects most required your expertise.
- Include some UX design sketches for the page, even if you made changes during development and the final result isn't pixel-perfect. You can use any design tool you like, whether Figma or pencil and paper.
- Identify what would be required to get this application ready for a production deployment.
